■ HANDLING DEVICES

• Preventing latch-up

Latch-up phenomenon may occur with CMOS IC, when a voltage higher than V_{CC} or lower than V_{SS} is applied to either the input or output terminals, or when a voltage is applied between VCC pin and VSS pin that exceeds the rated voltage. When latch-up occurs, a significant power-supply current surge results, which may damage some elements due to the excess heat, so great care must be taken to ensure that the maximum rating is never exceeded during use.

• Treatment of unused input pins

Do not leave an unused input pin open, since it may cause a malfunction. Handle by, for example, using a pull-up or pull-down resistor.

• Power pins

In products with multiple V_{CC} and V_{SS} pins, the pins of the same potential are internally connected in the device to avoid abnormal operations including latch-up. However, you must connect the pins to the same potential power supply and a ground line externally to lower the electro-magnetic emission level, to prevent abnormal operation of strobe signals caused by the rise in the ground level, and to conform to the total output current rating.
Moreover, connect the current supply source with the V_{CC} and V_{SS} pins of this device at the low impedance. It is also advisable to connect a ceramic capacitor of approximately 0.1 μF as a bypass capacitor between V_{CC} and V_{SS} near this device.

• Crystal oscillator circuit

Noise near the X0 and X1 pins may cause the device to malfunction. Design the printed circuit board so that X0,X1, the crystal oscillator (or ceramic oscillator), and the bypass capacitor to ground are located as close to the device as possible.
It is strongly recommended to design the PC board artwork with the X0 and X1pins surrounded by ground plane because stable operation can be expected with such a layout. Please ask the crystal maker to evaluate the oscillational characteristics of the crystal and this device.

• About mode pins (MD0 to MD2)

These pins should be connected directly to V_{CC} pin or V_{SS} pin.
Design the printed circuit board such that the pull-up/down resistance stays low, as well as the distance between the mode pins and power supply or GND pins is as short as possible and the connection impedance is low, when the pins are pulled-up/down such as for switching the pin level and rewriting the Flash memory data. It is because of preventing the device erroneously switching to test mode due to noise.

• Operation at start-up

Be sure to execute setting initialized reset (INIT) with INITX pin immediately after start-up.
Immediately after that, also, hold the "L"-level input to the INITX pin for the stabilization wait time required for the oscillator circuit to take the oscillation stabilization wait time for the oscillator circuit and the stabilization wait time for the regulator (For INIT via the INITX pin, the oscillation stabilization wait time setting is initialized to the minimum value).

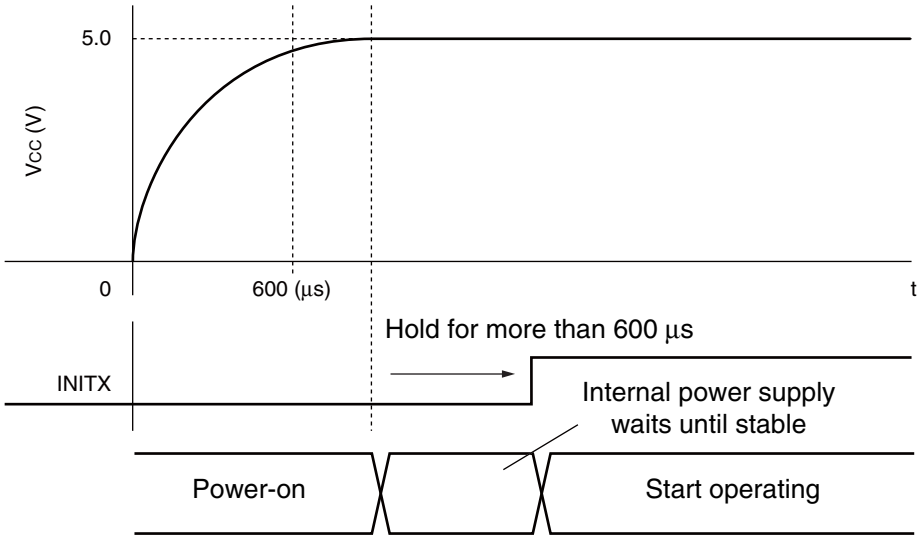
• Notes upon power-on sequence

It requires more than 600 µs (between 0.0 V to 5.0 V) to rise voltage upon power on in order to prevent the device malfunction caused by the overshooting in the built-in voltage step-down circuit.

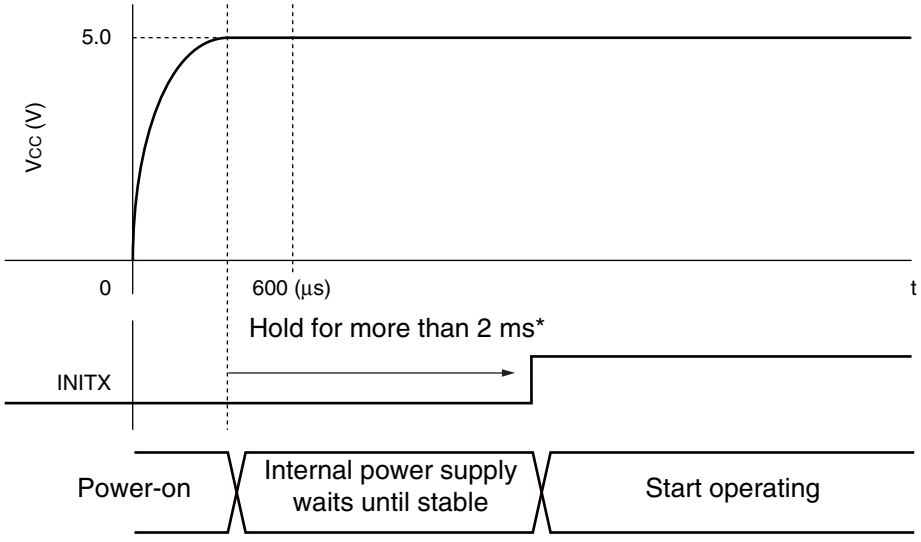
After the supply voltage is stable (voltage is risen) , it takes 600 µs until internal supply is stable. Hold the input to the INITX pin during that period.

If it takes less than 600 µs (between 0.0 V to 5.0 V) for power up, it requires 2 ms* until internal supply is stable after voltage supply is stable (voltage is risen) . Hold the input to the INITX pin during that period.

CASE : voltage rising time is more than 600 µs (0.0 V to 5.0 V)



CASE : voltage rising time is less than 600 µs (0.0 V to 5.0 V)



* : In case of which it takes less than 600 µs (between 0.0 V to 5.0 V) to rise voltage, the time to make internal power supply stable is proportional to the capacitance value of the bypass capacitor for the pin C.
It takes 2 ms if the pin C = 4.7 µF; 4 ms if the pin C = 9.4 µF.

• Order of power turning ON/OFF

Use the following procedure for turning the power on or off. If not using the A/D converter, connect AV_{CC} =V_{CC} and AV_{SS} = V_{SS}. Turn on the power supply in the sequence V_{CC} → AV_{CC} → AVRH, and turn off the power in the reverse sequence.

• Source oscillation input when turning on the power

When turning the power on, maintain the clock input until the device is released from the oscillation stabilization wait state.

• Cautions for operation during PLL clock mode

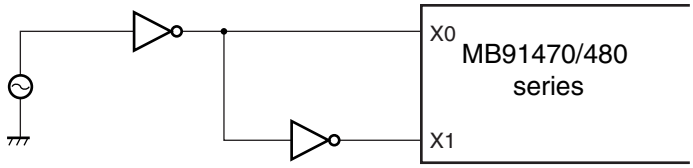
Even if the oscillator comes off or the clock input stops with the PLL clock selected for MB91470/480 series, MB91470/480 series may continue to operate at the free-run frequency of the PLL's internal self-oscillating oscillator circuit.
Performance of this operation, however, cannot be guaranteed.

• Using an external clock

When using an external clock, you must always input clock signals with opposite phase from X0 pin to X1 pin simultaneously. However, as the X1 pin halts with an output at the "H" level during stop mode, insert a resistor of approximately 1 kΩ externally to prevent a conflict between the two outputs if using stop mode (oscillation stop mode).

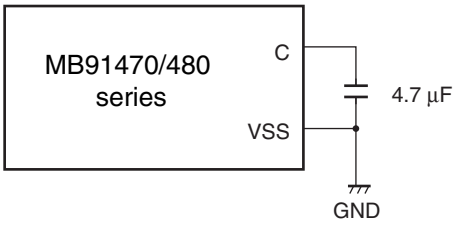
The figure below shows an example of how to use an external clock.

• Example of Using an External Clock



• C pin

As MB91470/480 series includes an internal regulator, always connect a bypass capacitor of approximately 4.7 µF to the C pin for use by the regulator.



• Software reset on the synchronous mode

Be sure to meet the following two conditions before setting 0 to the SRST bit of STCR (standby control register) when the software reset is used on the synchronous mode.

- Set the interrupt enable flag (I-Flag) to interrupts disabled (I-Flag=0).
- Not used NMI

■ MEMORY SPACE

1. Memory Space

The FR family has 4 Gbytes of logical address space (2^{32} addresses) available to the CPU by linear access.

• Direct Addressing Areas

The following address space areas are used as I/O areas.
These areas are called direct addressing areas, in which the address of an operand can be specified directly by the instruction. The size of directly addressable areas depends on the length of the data being accessed as shown below.

→ byte data access : 000H to 0FFH
→ half word data access : 000H to 1FFH
→ word data access : 000H to 3FFH

2. Memory Map

■ MODE SETTINGS

The FR family uses mode pins (MD2 to MD0) and mode data to set the operation mode.

1. Mode Pins

The MD2 to MD0 pins specify how the mode vector fetch and reset vector fetch is performed.
Settings other than those shown in the following table are prohibited.

Mode Pins			Mode name	Reset vector access area	Remarks
MD2	MD1	MD0			
0	0	0	Internal ROM mode vector	Internal	
0	0	1	External ROM mode vector	External	The bus width is set by mode register.

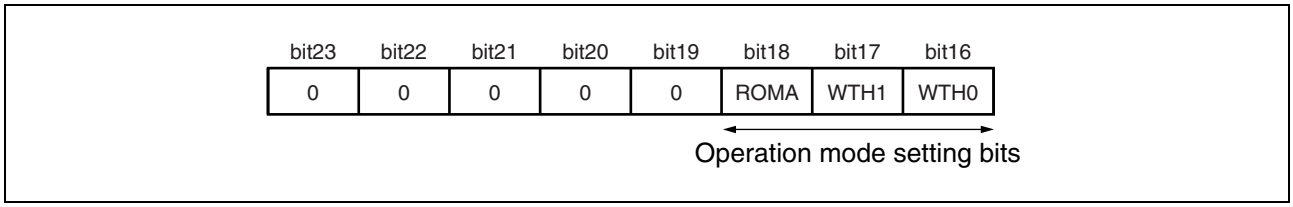
2. Mode data

The data that is written to the internal mode register (MODR) by the mode vector fetch is called mode data.

After the mode register is set, the device runs in the operating mode specified by this register.

The mode data is set by all of the reset sources. User programs cannot set the mode register.

<Details of mode data description>



[bit 23 to bit 19] Reserved bits

Be sure to set these bits to “00000_B”.

Operation is not guaranteed if these bits are set to a value other than “00000_B”.

[bit 18] ROMA (Internal Flash/ROM enable bit)

This bit configures whether the internal Flash/ROM area (8 0000_H to F $FFFF_H$) is enabled.

ROMA	Function	Remarks
0	External ROM mode	Internal Flash/ROM area (8 0000_H to F $FFFF_H$) is used as an external area.
1	Internal ROM mode	Internal Flash/ROM area (8 0000_H to F $FFFF_H$) is enabled.

[bit 17, bit 16] WTH1, WTH0 (Bus width specification bit)

These bits configure the bus width in external bus mode.

In external bus mode, this value is set to the DBW1 and DBW0 bits of AWR0 (CS0 area).

WTH1	WTH0	Function	Remarks
0	0	8-bit bus width	External bus mode
0	1	16-bit bus width	External bus mode
1	0	—	(Setting prohibited)
1	1	Single chip mode	Single chip mode

3. Note

The mode data set in the mode vector must be stored as byte data at 0x000FFFF8H. The data should be located in the highest byte from bit 31 to bit 24 because the FR family uses big endian byte ordering.

■ PIN STATUS IN EACH CPU STATE

Terms used as the status of pins mean as follows.

- Input enabled
  Means that the input function can be used.

- Input disabled
  Indicates that the input function cannot be used.

- Input fixed to “0”
  A state of a pin, in which "0" is transmitted to internal circuitry, with the external input shut off by the input gate adjacent to the pin.

- Output Hi-Z
  Means to place a pin in a high impedance state by disabling the pin driving transistor from driving.

- Preserving the previous state
  Means to output the state existing immediately prior to entering this mode.
  That is, to output according to an internal resource with an output when it is operating or to preserve an output when the output is provided, for example, as a port.

- Input enabled when external interrupt function selected and enabled
  Inputs are allowed only when the pin is configured as an external interrupt request input pin and the external interrupt request is enabled.

WARNING: The recommended operating conditions are required in order to ensure the normal operation of the semiconductor device. All of the device's electrical characteristics are warranted when the device is operated within these ranges.

Always use semiconductor devices within their recommended operating condition ranges. Operation outside these ranges may adversely affect reliability and could result in device failure.

No warranty is made with respect to uses, operating conditions, or combinations not represented on the data sheet. Users considering application outside the listed conditions are advised to contact their representatives beforehand.

Notes :
- The above figures do not guarantee the accuracy between each unit.
- Output impedance of the external circuit ≤ 2 kΩ
- AVRHn = AVRH3, AVRH4

- **External impedance and sampling time of analog inputs**
  - The A/D converter is fitted with a sample and hold circuit. If the external impedance is so high that there is not sufficient time for sampling, the internal sample and hold capacitor will not fully charge to the analog voltage, and the precision of the A/D conversion will be adversely affected. Therefore, in order to satisfy the A/D conversion precision specifications, either adjust the register values and operating frequency or reduce the external impedance so that the sampling time is greater than the minimum value as given by the relationship between external impedance and minimum sampling time. If you are still unable to hold enough sampling time, connect a capacitor of about 0.1 µF to the analog input pin.

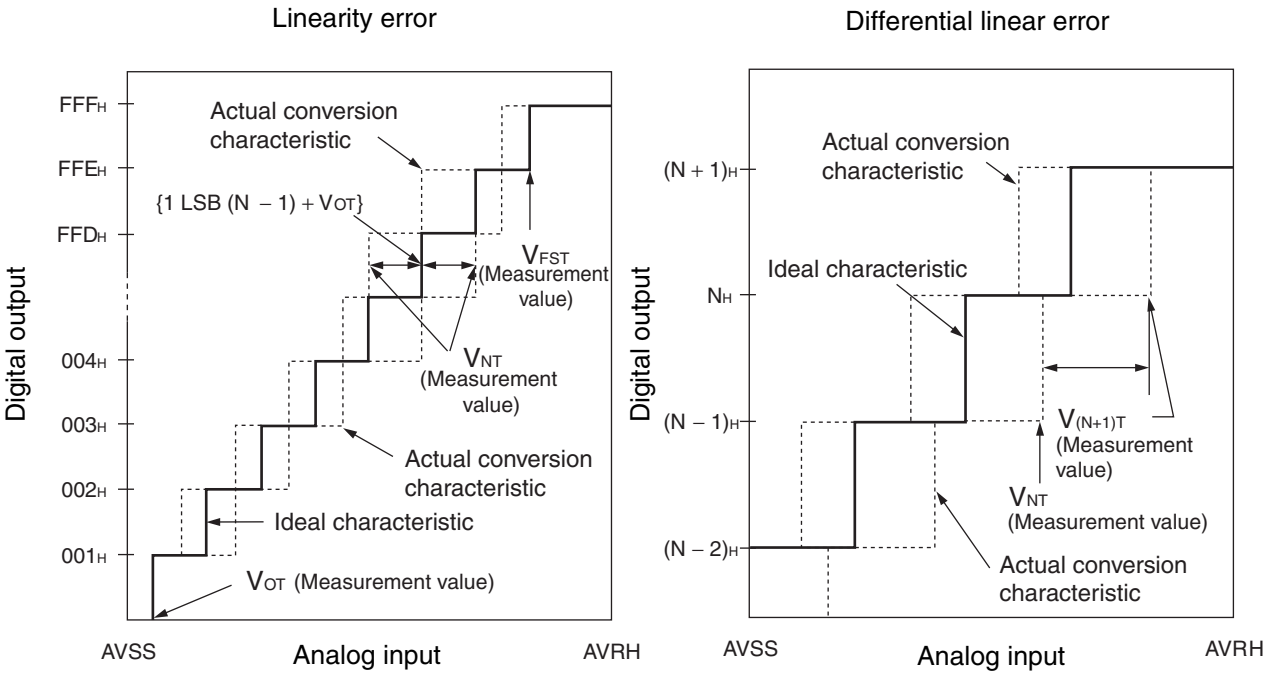
• **Definition of 12-bit A/D Converter Terms**

- Resolution : Analog variation that is recognized by the A/D converter.
- Linearity error : Deviation between the line connecting zero transition point (000000000000←→000000000001) and full-scale transition point (111111111110←→111111111111) and actual conversion characteristics.
- Differential linear error : Deviation from the ideal value of input voltage necessary to the output code by ILSB.



$$\text{Linear error in digital output } N = \frac{V_{NT} - \{1\ LSB' \times (N-1) + V_{OT}\}}{1\ LSB'}\ [LSB]$$

$$\text{Differential linear error in digital output } N = \frac{V_{(N+1)T} - V_{NT}}{1\ LSB'} - 1\ [LSB]$$

$$1\ LSB = \frac{V_{FST} - V_{OT}}{4094}$$

N : A/D converter digital output value
V_{OT} : Voltage at which digital output changes from 000_H to 001_H.
V_{FST} : Voltage at which digital output changes from FFE_H to FFF_H.
V_{NT} : Voltage at which digital output changes from $(N-1)_H$ to N_H.
